(54) Title: MICROWAVE APPLICATOR AND METHOD OF OPERATION

(57) Abstract

An apparatus and method for non-invasive removal of target tissues, is disclosed. The apparatus includes a microwave applicator antenna element array (20) for introducing a plurality of cylindrical, quasi-transverse electromagnetic surface waves adjacent the target tissue. Through successive phase shifts, the electromagnetic surface waves are brought to converge on a focal point within the target tissue, thereby elevating the temperature of the tissue. In one application the microwave applicator is used for reducing fatty tissue within a subcutaneous fatty layer by taking into account the differing dielectric constants of the adjacent skin and muscle layers. By launching a wave trapped between the skin layer and the muscle layers, a converging cylindrical wave is produced which includes a column of high density along a line extending from the skin fat interface to the muscle fat interface. The effect of the column of high density is to raise the temperature of adipose cells to a level at which fat cell necrosis occurs. In operation, a cooling bolus (34) coupled to the applicator actively maintains skin surface temperature below a level at which cell damage or discomfort would occur.

MICROWAVE APPLICATOR AND METHOD OF OPERATION

Field of the Invention

This invention relates to a microwave applicator and the operation of that applicator to achieve hyperthermia and, more particularly, to the employment of a microwave antenna array for use in, for example, thermal adipocytolysis for non-invasive reduction of adipose tissue.

Background of the Invention

Hyperthermia involves the heating of living tissues for therapeutic purposes, such as for increasing blood flow to a particular part of the body. Hyperthermia has been used as a method of treating tumors by means of raising the temperature of the tumor locally, or in the region surrounding the tumor. Hyperthermia can also be effective in reducing adipose tissue through fatty cell necrosis.

Electromedical methods and apparatus for removing target tissue have been disclosed in conjunction with various surgical and therapeutic procedures, some of which are non-invasive. For example, U.S. Patent No. 4,527,550 to Ruggera et al. discloses a radio-frequency diathermy apparatus, including means for localizing the heat focus for eliminating tumor cells. U.S. Patent No. 4,397,313 to Vaguine discloses a microwave hyperthermia apparatus, including a means for focusing electromagnetic energy at a particular region of the body. U.S. Patent No. 3,958,559 to Glenn et al. discloses an ultrasonic transducer for focusing ultrasonic waves for non-invasive treatment of internal structures, for example, tumors, within the body.

Although these systems are useful for non-invasive treatment of target tissues, none are specifically directed to the more general application of removing either tumor cells in deeper tissue layers or fat cells within a largely intact subcutaneous fat layer. In fact, each of these systems recognizes the inherent differences between fatty tissue and tumor tissue and teaches the need for avoiding damage to adipose and other normal tissues adjacent to the tumor. Vaguine and Glenn, for example, point to the differing heat tolerance of tumor cells in the context of preserving fatty and other cells adjacent the target tumor cells, not reducing them. Furthermore, the device disclosed by Vaguine uses an element field polarization more appropriate for treating deep tissues below the fat layer, rather than for treating the fat layer itself.

Accordingly, those skilled in the art would desire a generally applicable non-invasive microwave applicator that could be used to induce hyperthermia in living tissue for therapeutic purposes such as either tumor removal or fatty cell necrosis.

1 **Summary of the Invention**

 There is, therefore, provided in practice of the present invention a microwave applicator comprising an antenna element array, an electronic housing for enclosing circuit elements for providing and controlling microwave power, and a cooling bolus for conditioning the microwaves and cooling the skin surface upon application of the microwaves for removal of target tissue. The antenna elements are used for generating a transverse electromagnetic surface wave. For preferentially heating target tissue, the applicator includes a control circuit for adjusting the amplitude and phase of the antenna array elements for converging the transverse electromagnetic waves at the target tissue.

10 In an exemplary application, the applicator can be used to remove adipose tissue through hyperthermia-induced fatty cell necrosis. The method includes the steps of using the applicator to generate a cylindrical, converging, quasi-transverse electromagnetic surface wave within the fat layer by utilizing the differing dielectric and conductivity characteristics of the skin layer and muscle layers surrounding the fat layer. By launching a wave trapped between these layers from all directions surrounding an intended focus, a converging cylindrical wave is produced which includes a column of high density along a focal line within the fat extending from the skin-fat interface to muscle-fat interface. In operation, the amplitude and phase for the individual antenna elements on the microwave applicator are adjusted to move the focal line within a target fat region to be eliminated within the subject. Simultaneously with application, the cooling bolus actively cools the skin surface to prevent skin burns and acute pain. As a given fat region is treated, the applicator is moved and applied over adjacent regions until the desired fat reduction is achieved.

15 **Brief Description of the Drawings**

25 These and other features and advantages of the present invention will be better understood from the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, in which:

 FIG. 1 is a schematic diagram, partly in cross section, of a general purpose therapeutic microwave hyperthermia applicator according to the present invention for non-invasive application of a thermal dose to target tissue;

30 FIG. 1a is a schematic diagram of an alternate embodiment of the microwave applicator of FIG. 1;

 FIG. 2 is a schematic diagram depicting skin with its adnexa, the subcutaneous fat layer, and a portion of the underlying muscle layers;

35 FIG. 3 is a diagram of a microwave applicator according to the present invention and a cross-sectional view of a typical human abdomen showing the skin, subcutaneous fat layer, underlying muscle layers, and viscera in conjunction with a microwave applicator according to the present invention;

1 FIGS. 4 and 4A are diagrams of a typical arrangement of antenna elements in the microwave applicator of FIG. 1;

 FIG. 5 is a diagram of a typical antenna element used in a preferred embodiment of the present invention;

5 FIG. 6 is a diagram of an alternative embodiment of antenna element;

 FIG. 7 is a circuit diagram of an exemplary antenna element feed and control system;

 FIG. 8 is a diagram of how to realize the variable gain amplifiers in FIG. 7 using a variable attenuator and a fixed-gain amplifier;

10 FIG. 9a is a circuit diagram of another exemplary control system for activating particular antenna elements of the type illustrated in FIG. 6; and

 FIG. 9b is a circuit diagram of an alternate embodiment of the control system of FIG. 9a.

Detailed Description

15 Referring to FIG. 1, a microwave applicator for inducing hyperthermia in target cells includes an antenna element array 20 having individual antenna elements 22 embedded in a ground plane 21. The array is coupled to an electronic housing, or feed distributional manifold 6, for enclosing electronic components and circuits required for production and control of microwave power. Computer control signals, bias voltages, amplifier power, and possibly microwave power carried through transmission lines are bundled in one or more flexible conduits 11.

20 For cooling the skin surface during microwave application, the applicator further includes a two-layered bolus 34. In one embodiment (see FIG. 1), a low-impedance layer 35, contacting the skin surface, is formed of a solid high-dielectric material, such as ceramic. 25 The range of dielectric constants suitable for the low impedance is from 40 to 60. A preferred range is from 45 to 55. A high-impedance layer 36 is formed of a thin-walled, low-or-high-dielectric constant vessel 3 through which a cooling fluid 4 is circulated by way of fluid inlet and outlet ports 5, 7. The cooling fluid is chosen to have a dielectric constant much lower than that of the low-impedance layer. The range of dielectric constants suitable for the high-impedance layer is from 4 to 7. A preferred range is from 5 to 6. 30

 The solid portion of the bolus is preferably thin-walled but does not have to be flexible. The liquid portion of the bolus is preferably non-toxic, and should have sufficiently low viscosity so as to allow it to be pumped through the bolus at a rate sufficient for thermal transfer. One suitable liquid includes powdered metals in water, e.g., titanium doped water.

35 To absorb surface waves incident on the ends of the bolus, part of the high-impedance bolus layer is directed upward along the side of the electronic housing to trap the waves. In addition, the ends of the low-impedance layer are integrally connected to a bounding ring of absorbing terminators 2 made of loss absorbing material for absorbing power in the surface

1 waves incident on the truncation of the applicator. In operation, the bolus acts as a heat
exchanger to maintain the temperature of the skin surface below about 140°F. Above this
temperature, unwanted damage to cells proximate the skin surface may occur. Preferably,
the skin surface temperature is maintained below 120°F to prevent discomfort. In addition
5 to acting as a heat exchanger, the bolus also conditions the microwaves as they pass from the
antenna array through the bolus, and helps to focus the microwaves. For optimal
conditioning and focusing, the overall dielectric constant of the bolus is preferably uniform.

Referring to FIG. 1a, in an alternative embodiment of the applicator, the low-
impedance layer 38 of the bolus is formed of a high dielectric shell 40 proximate the skin
10 surface through which a high-dielectric cooling fluid 42, such as water, is circulated. The
high-impedance layer 44 is formed of a solid lower dielectric material, such as a
polytetrafluoroethylene, barium titanate matrix, or by a ferrite material. In the alternate
embodiment, the range of dielectric constants suitable for the low-impedance layer and the
high-impedance layer are the same as those for the preferred embodiment described above.

15 The fundamental principle of operation of the microwave applicator is to generate a
plurality of cylindrical quasi-transverse electromagnetic surface waves proximate the target
tissue. Through successive phase shifts, the waves are brought to convergence, thereby
producing a column of high energy density within the target tissue. The effect of the column
of high density is to raise the temperature of target tissue to a level at which cell necrosis
20 occurs.

FIGS. 4 and 4A show the underside of the antenna element array 20 that is part of the
microwave applicator comprising a ground plane 21 and individual antenna elements 22.

Referring to FIG. 5, in a preferred embodiment, the individual antenna elements 22
of the array consist of circular microstrip antennas, recessed into the ground plane 21 so that
25 the circular patch 14 is flush with the surface of the ground plane. The elements are fed via
a coaxial feed 16 at the geometrical center of the patch through a dielectric or ferrite cylinder
15, whose electrical properties and diameter are chosen along with the electrical properties
of the substrate dielectric 13, to cause the element to resonate at the desired operating
frequency.

30 An electric vertical monopole-like mode is produced by the element with an equivalent
magnetic current 117 in the gap between the patch edge and the ground plane that is uniform
in the azimuthal direction. Additional matching of the final amplifier stage is accomplished,
if necessary, through an additional conventional matching network to which the coaxial feed
16 is attached. The interior field under the patch, which is proportional to the strength of
35 the equivalent magnetic current 117 (which determines the radiating properties of the
element), is sampled via capacitive coupling by the weakly coupled coaxial port 16a. The
purpose of the coaxial feed and the feedback loop is to obtain actual data during operation

1 of actual phase and amplitude. The coaxial feed would allow measurement of actual phase and amplitude.

Referring to FIG. 6, in an alternate preferred embodiment, a dual-feed circular patch antenna 37 is disclosed. The dielectric properties of the substrate material are chosen in this
5 embodiment to resonate the element in a horizontal dipole-like mode. In this mode, the equivalent magnetic current 19, produced when the antenna is fed at coaxial feed port 18, undergoes a change in direction along a nodal plane that bisects the circular patch. A second coaxial feed 17 is placed in this nodal plane. The second feed is capable of independently exciting a similar magnetic current distribution rotated, however, 90° about the center of the
10 patch. This rotated magnetic current produces an electric field in tissue whose transverse component (the component parallel to the plane of the patch) is orthogonal to the corresponding component produced by the other feed. Thus, by simultaneously feeding ports 17 and 18, any state of polarization can be produced.

The first preferred embodiment described above has the advantage of simplicity,
15 requiring half the number of amplifiers, feed ports, and phase shifters as the alternate preferred embodiment. It also has the advantage of producing only transverse magnetic fields. This is an electromagnetic field which lacks a component of magnetic field perpendicular to the plane of the patch. In contrast, the alternate preferred embodiment produces both transverse magnetic and transverse electric field types, the latter of which
20 lacks the desired component of electric field normal to the tissue planes. FIG. 4a illustrates the direction of average magnetic current in each of the elements that would have to be synthesized using appropriate amplitude and phase adjustment of the two ports of the dual-polarized element to launch a converging quasi-TEM cylindrical wave at the focal line 26. The required direction is obtained by constructing a line 24 between the projection 25
25 of the focal line 26 onto the aperture plane and the center 27 of a given dual-polarized element. The average required direction of magnetic current 23 is then perpendicular to the line 24. Thus, as the scan point varies within the target tissue, the polarization of the dual-polarized elements will have to be readjusted. The alternate preferred embodiment, however, has the advantage of flexibility for use in various target tissue, including tissue in
30 the adipose layer, or other target tissues or tumors in deeper tissue layers.

The overall system design of the exemplary embodiment using antenna elements 22 as shown in FIG. 5 is illustrated in schematic form in FIG. 7. The output of a common fixed-frequency oscillator 801 is amplified through a fixed gain amplifier 802, whose output is sampled by a directional coupler 811. The output of the main branch of the directional
35 coupler is split by a power-divider 803. This provides a phase-coherent input signal to each of the phase shifters and amplifiers that feed the radiating antenna elements. For example, the output of one branch of the power divider feeds a 0-360° variable-phase shifter 804 controlled by the dc control voltage in biasing line 812. The output of the phase shifter

1 enters a variable gain amplifier 805, whose gain is controlled by dc control voltage on a
biasing line 813.

Depending on the voltage-standing-wave mismatch tolerance of the final output
transistor in the variable-gain amplifier 805, an isolator 807 may or may not be included.
5 The output of the amplifier or the isolator, if present, is fed to the input port of an antenna
element 806 (element 22 in FIG. 5). The total internal field of the antenna element, which
depends both on the actual feed voltage applied to its own input and on the mutual coupling
between other antenna elements in the array, is sampled through a weakly coupled sample
port 808 (element 16a in FIG. 5). This signal is coupled through a single pole, multithrow
10 microwave switch 809, which is controlled by a control signal on line 814 to a phase-
amplitude comparator 810. This comparator sequentially compares the phase and amplitude
of each antenna to the phase and amplitude reference provided by the coupled port of the
phase shifter 811. The phase and amplitude of each antenna is provided by the coupled port
of the phase shifter 811. The phase and amplitude of each antenna is output as dc voltage
15 levels on lines 815 and 816. This information is provided to the controlling computer
through analog-to-digital converters. By using an appropriate control algorithm, the bias
voltage levels on the phase shifters and the variable-gain amplifiers can be adjusted so that
the actual amplitude and phase of the antenna array elements are brought to their desired
nominal levels. An exemplary Mathematica software program for developing a microwave
20 applicator control algorithm is attached hereto as Exhibit A.

The output power of the variable-gain amplifiers can be controlled by adjusting the
bias voltage on one or more amplifier stages through control voltage lines provided in
commercially available power modules. Alternatively, the attenuation of a voltage-controlled
analog or step attenuator 901, illustrated in FIG. 8, can be controlled by the bias voltage
25 placed on biasing line 903. The output of this attenuator feeds the input of a fixed-gain
amplifier 902.

Use of the alternative antenna element 37 illustrated in FIG. 6 requires the feed
network illustrated in FIG. 9a. In this case, the output of the main power-divider manifold
803 of FIG. 7 is further divided by a two-way power splitter 1001. The output of each port
30 of the power splitter feeds two identical phase-shifter, amplifier combinations. For example,
the output of one port feeds a voltage-controlled variable phase shifter 1002 with bias line
1003. The output of the phase shifter feeds the variable-gain amplifier 1004 with control-
voltage line 1005. The output of one amplifier feeds one of the two feed ports 1006 (element
17 in FIG. 6) of a dual-polarized circular microstrip antenna 1007 (element 37 in FIG. 6).
35 The output of the other amplifier 1009 feeds the second orthogonally placed feed port 1008
(18). By adjusting the amplitude and phase of each of the two branches, the net power in
each of the two orthogonal polarizations that the antenna element 1007 (37) produces can be
independently adjusted, yielding the desired polarization state at the desired amplitude and

1 phase. Alternatively, one of the phase shifters 1001 can be placed between the output of the
main power-divider manifold 803 of FIG. 7 and the two-way power divider 1002, as
illustrated in FIG. 9b.

5 As discussed, the microwave applicator according to the present invention is useful for
inducing hyperthermia in a variety of applications. The most straightforward application
would involve using the microwave applicator to warm a part of a patient's body so as to
increase blood flow to the area. Another such application involves the use of the microwave
applicator to remove adipose tissue.

10 Adipose tissue, more commonly known as fat, is formed of cells containing stored
lipid. In humans, adipose tissue is widely distributed in subcutaneous tissue located between
an outer skin layer and inner muscle layers. Fat cells are relatively large, ranging up to 120
microns in diameter. Adipocytes represent a non-renewing tissue. An increase in adipose
mass is mediated by cellular hypertrophy, or enlargement of individual cells, rather than
cellular hyperplasia, or increase in numbers of adipocytes.

15 An excess of adipose tissue, a condition known as obesity, may be undesirable in that
it gives rise to various health problems in human beings, both physical and psychological.
The former includes an increased risk of heart disease, high blood pressure, osteoarthritis,
diabetes, and other unhealthful conditions. The latter can result in a deterioration of an
individual's self image and work and social relationships because excess fatty deposits may
20 be perceived by the individual, and those with whom the individual interacts, as having an
unsightly appearance. Dieting and behavior modification are helpful for reducing body fat,
but it is often difficult to differentially remove fat from selected areas of the body, such as
the abdomen or buttocks, while retaining desirable fat in other parts of the body. Moreover,
many cannot maintain the regimen of sustained dieting combined with exercise to remove
25 undesired fat from these areas. In such circumstances, spot fat reduction may be needed to
eliminate relatively localized fat deposits that may be otherwise difficult to remove by dieting
or exercise.

Thus, there exists a need for improved methods of removing adipose tissue, both for
treating obesity and for cosmetic purposes. Liposuction has been used primarily for cosmetic
30 fat removal and, occasionally, in an attempt to treat obesity. Liposuction involves purely
mechanical means for extracting adipose tissue from the body. This is accomplished by the
percutaneous insertion of a tube catheter into the fatty tissue and by application of suction
to the proximal end of the tube. Although effective in the cosmetic removal of fat in many
cases, the procedure suffers from numerous side effects due to the highly invasive nature of
35 the process. These side effects include serious infection, fat embolism, and complications
of anesthesia.

Some non-invasive systems have been disclosed for reducing fatty deposits in humans.
These systems, however, suffer from various drawbacks and limitations that make them

1 undesirable or unusable as disclosed for clinical application. For example, U.S. Patent No.
4,556,442 to Mabuchi et al. describes a massager in which the skin surface is patted
repeatedly for eliminating or loosening fat in the subcutaneous layer. The massaging is
augmented by feeding warm air into the skin surface being patted. The effectiveness of this
5 device as a means for fat removal is suspect.

U.S. Patent No. 5,295,955, issued to Rosen et al., discloses a method and apparatus
for using microwaves to soften fat cells. Rosen, however, involves using microwaves in
conjunction with an invasive liposuction procedure to completely eliminate the cells. More
specifically, Rosen discloses a microwave generator for localizing radiation from an antenna
10 into the fatty tissue adjacent the suction portion of the liposuction catheter. The microwaves
are used to heat and soften the adipose tissue so less mechanical force is required for its
removal. Therefore, although Rosen discloses a method for reducing adipose tissue using
microwaves, this method and apparatus still suffers from the disadvantages of invasive
procedures involved in liposuction.

15 U.S. Patent No. 5,143,063, issued to Fellner, discloses a method for removing adipose
tissue from the body by focusing radiant energy, such as RF, microwave, or ultrasound
energy, toward fat cells. Fellner recognizes that fatty cell necrosis ("death") can be achieved
by causing disruption within the adipose structure, e.g., through hyperthermia. However,
Fellner fails to disclose an apparatus for implementing the disclosed method in a clinically
20 operable manner. Instead, regarding the destruction of fat cells, Fellner teaches that "...one
of the above prior art systems may be employed to supply localized or focused radio-
frequency energy, microwave energy, or ultrasound energy to the tissue to be destroyed."
In the same disclosure, however, Fellner previously points out that the referenced systems
had been employed specifically to avoid normal tissue damage, including damage to the
25 subcutaneous fat layer.

In particular, Fellner fails to disclose how the outer skin surface within the microwave
path can be cooled sufficiently to prevent skin burns. There is no disclosure on how the
microwave or acoustic energy can be focused on the adipose tissue without unduly heating
or damaging surrounding subsurface skin structures and muscle layers, or endangering deep
30 viscera. Nor is there any disclosure of how to prevent treatment-limiting, thermal-induced
acute pain or discomfort. Fellner further fails to disclose an apparatus or method for
producing the microwaves or for controlling and optimizing the power distribution of the
microwaves in the irradiated tissues or for the preferential deposition of energy within the
subcutaneous fat layer. Finally, there is minimal disclosure of an effective procedure for
35 limiting and distributing the volume of adipose damage to allow physiological repair
mechanisms to remove necrotic cells without inducing potentially disfiguring scarring of
subcutaneous tissues.

1 In the context of fat removal, those skilled in the art would desire a clinically usable apparatus and method for non-invasively reducing or eliminating unhealthful or unsightly adipose tissue without the undesirable side effects of liposuction and without the potential dangers of hyperthermia devices specifically designed to treat tumors.

5 The microwave applicator according to the present invention can be used to effectively remove fat cells by inducing hyperthermia in the adipose layer without the use of invasive procedures and without damage to surrounding normal tissue in the adjacent skin and muscle layers. FIGS. 2 and 3 show cross-sections of a typical human body showing the skin layer 101, the muscle layers 103, and the fat layers 102. Also shown are the skin-fat interface 104 and the muscle-fat interface 107. For fat removal, the fundamental principle of operation of the present invention is the generation of a cylindrical converging quasi-transverse electromagnetic surface wave within the fat layer by taking into account the differing dielectric constants and heat capacities of the tissues in the adjacent skin and muscle layers. As shown in FIG. 3, the microwave applicator may be designed with a curved surface to fit against body contours.

15 The antenna element arrays shown in FIGS. 5 and 6 are both sufficient to induce hyperthermia in the adipose layer. The embodiment of FIG. 5 produces an electric field component that is perpendicular to the plane of the patch, which is most important for the application of preferentially heating the fat layer. The embodiment of FIG. 6 is useful for treating deeper tissues, although it can be used for heating the fat layer by coupling to converging cylindrical waves.

20 In an exemplary embodiment, assuming a fat layer thickness of 3 cm, the dimensions of the bolus are about 21 cm x 21 cm. In a preferred embodiment, optimal excitations for the antenna elements are determined as a function of fat-layer thickness and the dimensions of the bolus. Mathematica software code for identifying the optimal excitations for the adipose tissue reducing application is attached hereto as Exhibit A.

25 The dimensions of the housing for the exemplary embodiment are about 20 cm x 20 cm and the overall dimensions of the antenna array are about 15 cm x 15 cm. In the exemplary antenna array, there are 73 individual antenna elements. Each antenna element has a radius of 0.76 cm and is about 1-2 mm thick. Preferably, the overall dimensions of the array should be as small as possible to provide spot fat reduction in hard-to-reach areas while still being effective to launch a converging cylindrical surface wave within the fatty layer. At the present time, the limiting constraint for the dimensions of the bolus is the radius of the antenna element. The thickness of the bolus is chosen to optimally condition the microwaves while effectively cooling skin surface during application.

30 Those skilled in the art would appreciate that various alternations and modifications to the described invention could be made without departing from the scope of the present invention as set forth in the claims. For example, in operation, it is possible to turn off

1 certain antenna elements to access hard-to-reach areas. Also, although described with respect
to fatty cell removal, the microwave applicator according to the present invention may be
used for general therapeutic purposes involving hyperthermia.

WHAT IS CLAIMED IS:

1. A microwave applicator for inducing hyperthermia in target tissue comprising:
a plurality of antenna elements arranged in an array for generating a transverse electromagnetic surface wave; and
means for adjusting amplitude and phase of the antenna array elements for converging the transverse electromagnetic waves at the target tissue, thereby heating the target tissue.
2. The apparatus of claim 1 wherein the antenna element array comprises:
a ground plane; and
wherein the antenna elements are attached to the ground plane, each antenna element comprising a circular microstrip antenna.
3. The apparatus of claim 1 wherein each antenna element comprises a dual-feed patch antenna for resonating the antenna element in a substantially horizontal mode.
4. The apparatus of claim 1 further comprising a heat exchanger coupled to the antenna element array for maintaining temperature of skin surface below about 140°F, the heat exchanger comprising:
a low-impedance layer formed of a solid dielectric material; and
a high-impedance layer coupled to the low-impedance layer including a vessel through which fluid is circulated.
5. The apparatus of claim 1 further comprising a heat exchanger coupled to the antenna element array for maintaining temperature of skin surface below about 140°F, the heat exchanger comprising:
a low-impedance layer including a shell through which fluid is circulated; and
a high-impedance layer formed of solid dielectric material coupled to the low-impedance layer.
6. A method for non-invasively removing target tissue, the method comprising the steps of:
introducing a plurality of electromagnetic surface waves on a plane dissecting the target tissue, substantially within the adipose layer;
converging the electromagnetic surface waves on the target tissue, thereby heating the target tissue.

1 7. The method of claim 6 wherein the step of introducing the electromagnetic surface waves comprises generating a cylindrical converging quasi-transverse electromagnetic surface wave substantially within an adipose layer.

5 8. The method of claim 6 wherein the step of introducing the electromagnetic wave comprises generating a wave having selective absorption within an adipose layer.

Y		2-8
Y	US, A, 5,143,063 (FELLNER) 01 September 1992, see column 3 lines 8-32.	6-8
Y	US, A, 5,101,836 (LEE) 07 April 1992, see column 2 line 28 to column 3 line 68.	1-8
Y	DE, A, 3320 990 (KNOCHER) 13 December 1984, see Abstract.	3

☐ Further documents are listed in the continuation of Box C.☐ See patent family annex.

* Special categories of cited documents:

A document defining the general state of the art which is not considered to be part of particular relevance

E earlier document published on or after the international filing date

L document which may throw doubt on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

O document referring to an oral disclosure, use, exhibition or other means

P document published prior to the international filing date but later than the priority date claimed

T

later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X

document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y

document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

Z

document member of the same patent family

Date of the actual completion of the international search

28 AUGUST 1996

Date of mailing of the international search report

27 SEP 1996
